

Run Fits: Gap Integrity, Force, Spill, and Box Math

Why a defensive end throws himself under a pulling guard on purpose, and how eleven defenders turn a run into arithmetic

First-and-10, early in the third quarter. The offense runs power to the right: a guard pulls from the left side, the fullback races toward the defensive end man on the right, and for a split second there is a hole outside the tight end that looks big enough to drive a truck through. Then the end man does something that looks like a mistake. Instead of standing up to the fullback, he throws himself *underneath* him, toward the inside, and the two of them go down in a heap right where the hole was supposed to be. The pulling guard has nowhere to go. The running back bounces outside, finds green grass for a stride, and is met by a safety who was twelve yards deep when the ball was snapped. Gain of two. The analyst says, “Great fit by the defense.” Nobody on the defense made a spectacular play. Nobody beat a block. So what, exactly, was great? This chapter is the answer: a run defense is not eleven men chasing the ball, but eleven *assignments* that add up, and the end who “lost” that collision was the most important part of the sum.

You’ll be able to:

- Account for every gap against a formation and name the defender who owns each one, including the gap a safety brings with him when he comes down.
- Find the force defender on each side before the snap, and say from the coverage shell whether he is likely to be an end, a linebacker, a safety or a cornerback.
- Tell spill from box (squeeze) when a pulling guard or fullback arrives, and say where the ball should go next and who must be waiting there.
- Do the box math, including the quarterback who runs and the safety who rotates down at the snap, and say who the free defender is.
- Explain how a defense fits zone, power and the zone read, why the gap exchange exists, and what each answer costs.
- Read a chart of rushing EPA by box count, and explain why a defense that keeps two safeties deep and invites the run is making a reasonable bet.

i You’ll need

- **Linebackers and the Second Level:** how a linebacker reads his key (the blocker or back he watches to learn where the play is going), flow (fast flow toward the play, slow flow away from it), and the ways he gets to his gap: fill (downhill into a gap) and scrape (sideways behind the line to a gap farther out).
- **Option Football:** the read key (the defender the quarterback reads instead of blocking), the zone read, and the scrape exchange, which this chapter rebuilds from the defense’s side.
- Also useful: Gap and Power Runs (power, the kick-out and the puller); A First Look at Defense (the box, box count, light and loaded boxes, one-high and two-high shells); and Defensive Line Play (how a lineman fights a down block, setting the edge and contain).

How to read the diagrams. Offense is blue circles, defense orange squares, and *left* and *right* always mean the offense’s left and right. On offense, C is the center (the other four linemen are unlettered), Q the quarterback, R the running back, F the fullback, Y the tight end, and X, Z and H receivers. Defensive linemen are labelled by their technique number (5, 3, 1), S, M and W are the Sam, Mike and Will linebackers, \$ is the nickel back, CB a cornerback, and FS and SS the free and strong safeties. Blue lines ending in a short bar are blocks; orange arrows are where defenders go; the thick dark-blue arrow is the ball carrier. In the frame strips, faint lines are where each player has been.

What a run fit is

Start with the offense, because run defense only makes sense as an answer to it. Every run play in Part 3 is built around one of two ideas. Either it creates a *crease* the defense did not expect (zone’s moving wall and cutback), or it creates an *extra blocker* at one spot (power’s pulling guard, the fullback on an iso, the quarterback’s read on the option). Both ideas attack the same weakness: a defender who is not where his teammates think he is.

So the defense's first answer is not a technique or a tackle. It is a plan. A **run fit** is the defense's plan for which defender takes which gap or job against a run, and also the act of carrying it out: each defender getting to his gap after the snap, on the correct side of whoever is blocking him. Coaches use the word both ways. "Our fits were bad" means people went to the wrong places; "he fit it perfectly" means one player arrived in his gap at the right moment, on the right shoulder.

The principle underneath every fit has a name of its own: **gap integrity**. Every gap the offense can run through has exactly one defender responsible for it, and each defender stays in his gap until the ball shows him where it is going. "Exactly one" cuts both ways. A gap with nobody in it is an obvious problem: that is where the long run goes. A gap with *two* defenders in it is the same problem in disguise, because the defense only has so many players. If two defenders are in the B gap, some other gap is empty, and a good running back will find it.

You met the counting in Defensive Line Play: against a formation with one tight end there are seven gaps along the line (two A gaps either side of the center, two B gaps, two C gaps, and a D gap outside the tight end), and a one-gap defense puts one defender in charge of each. That count was the static version. Run fits are what happens when the count starts moving, and it moves for three reasons:

1. **Blockers carry gaps with them.** A gap is not a patch of grass; it is the space between two blockers. When the tight end blocks down on the man inside him, the C gap slides inward with him, and a new space opens outside.
2. **Backs add gaps.** A fullback who runs to the line, or a guard who pulls, is one more blocker at one spot, and the space beside him is one more gap. Coaches say *every back in the backfield can add a gap*. Power's whole point is to create a gap at the point of attack that the defense did not have a man for before the snap.
3. **The defense moves too.** Linemen slant, linebackers blitz, safeties rotate. Each of those moves takes a defender out of one gap and puts him in another, so somebody else has to inherit the gap he left.

A fit is the defense's way of keeping the count right *while* all of that happens. Before the snap, each defender knows his gap. After it, each knows how his gap changes when he sees a particular block: if the tackle in front of me blocks down, my gap is outside; if the guard pulls, the linebacker behind me fast-flows and I inherit his. The names you will learn in this chapter (force, spill, box, alley) are the vocabulary of those changes.

! Why it exists

A defense has eleven players and the offense knows where the ball is going; the defense does not. Run fits exist so that the defense does not need to know. If every gap has an owner and every owner knows how his gap moves when the blocking changes, the ball can go anywhere and somebody is waiting. The price is discipline. A fit only works if all eleven players do their job *instead of* chasing the ball, which means trusting the man next to you. The most talented player on the field can wreck a defense by "making a play" outside his gap and leaving it empty.

i Madden vs. real life

In Madden, the move every user learns is to grab the safety, wait for the handoff and sprint at the ball carrier. It works because the computer plays the other ten defenders' gaps perfectly. In real football, a player who leaves his gap to make a play is the most common reason for a long run, and coaches grade it as a missed assignment even when he makes the tackle. When you see a 60-yard run on a broadcast, rewind to the snap and look for the defender who ran to the wrong side of a block. It is rarely the man who missed the tackle at the end.

Force: who turns the ball back inside

Every run has an inside and an outside, and the outside is where the defense has fewest bodies. So before anyone talks about gaps, the defense names one player on each side of the ball whose job is the outside edge. He is the **force defender**, or "the force": the defender responsible for keeping the ball carrier from getting outside him on a run to his side and for turning (*forcing*) the ball back inside, toward the teammates who are chasing it. He does not have to make the tackle. He has to make the runner change direction, back into the crowd.

You have met two cousins of this idea. In Defensive Line Play, to **set the edge** was a *technique*: the outermost defender on the line takes on a blocker with his outside arm free so the run can't get outside him. **Contain** was a rule about the quarterback escaping the pocket or running a bootleg. Force is a *role*. It belongs to whichever defender the call assigns, and the call changes from play to

play. Sometimes the force is the defensive end, setting the edge exactly as 05-01 drew it. Often it is an outside linebacker, a nickel back or a safety a few yards outside the end. In some coverages it is a cornerback.

Why would a cornerback be the force? Because the coverage decides who is free. A defender who has a deep zone to protect cannot also come up to the line to turn a run inside; a defender with a short zone, or with no zone at all, can. That is why the first question to ask about a run defense is not “who’s in the box?” but “what are the safeties and corners doing?” Two common answers, which you will see drawn in full in the coverage chapters:

- **Safety force (Cover 3, “sky”).** One safety plays the deep middle; the other comes down to the strong side, outside the tight end, and becomes the force. The corners are deep, so they cannot be. This is the eighth man in the box, the shape of Cover 3 and its sky rotation.
- **Corner force (Cover 2, “cloud”).** Both safeties stay deep, splitting the field in halves. The corners have no deep zone, so they sit at about five yards, a step outside the widest receiver, and come up to force the run. This is the classic shape of Cover 2.

Who stands just *inside* the force is the next question, and it is the subject of the next section, but you can see both answers at once in Figure 1.

Figure 1: Force and alley depend on the coverage. Same power-side picture, run to the right. Left, Cover 3 ‘sky’: the strong safety has come down outside the tight end and is the force (purple ring), coming up outside-in; the free safety comes down from the deep middle to fill the alley (green ring, green lane). Right, Cover 2 ‘cloud’: both safeties stay deep, the cornerback squats at five yards and is the force, and the safety on that side fills the alley from his deep half. The man outside forces; the man inside him fills the alley.

The force has a hard job, and the technique he uses is mostly patience. He comes up *outside-in*: he approaches the ball from outside its path, keeping his inside shoulder toward the runner and his outside arm free, never letting the runner’s helmet get to his outside. Come up too fast and too far inside, and a back with any speed simply runs around him, a “leaky” or “soft” edge. Come up too slowly, and the back turns upfield inside him for seven yards before anyone arrives. A good force player is the defense’s answer to two of the offense’s most dangerous plays: the outside run that wins the corner, and the bounce, which is a run that was designed to go inside and ends up outside. The bounce is the force’s specialty, and it is where the next idea comes in.

Common misconception

“The defensive end is always responsible for the outside.” Sometimes he is, and then he sets the edge. But in many calls the end is told to do the opposite: take on blocks *inside* and let somebody else have the outside. Whether the end is the force or not is decided by the call and the coverage, and you can often tell before the snap. If a safety or a corner is standing five to seven yards deep just outside the tight end, the end probably isn’t the force.

Spill or box: two ways to meet a kick-out

Now go back to the play this chapter opened with. Power's kick-out block, from Gap and Power Runs, asks a question of the end man on the line (here, the Sam linebacker standing up outside the tight end): a fullback is coming at you from the inside, and a pulling guard and the running back are right behind him. What do you do?

There are two answers, and every defense teaches both.

Spill. The defender attacks the blocker's *inside* half. He gets his outside shoulder and arm across the blocker's body, under him, toward the hole, a move coaches call a *wrong arm* (or wrong shoulder), because it uses the arm a defender is usually taught to keep free. He is not trying to win. He is trying to make a pile in the hole: his body, the fullback's body, and soon the pulling guard, who arrives to find his lane full of bodies. The running back, who was following that guard, has nowhere to go inside, so the ball *spills* outside, sideways along the line.

Box technique, also called **squeeze**. The defender keeps his outside arm free, meets the blocker with his inside shoulder, and drives him back inside, squeezing the hole from the outside so it gets smaller and smaller. He is "boxing" the ball in: it cannot get outside him, so it has to stay inside, where the linebackers are filling. (Don't confuse box *technique* with *the* box, the area near the ball where defenders are counted. The words are unrelated; football just reuses them.)¹

The two techniques send the ball to opposite places, and that is the whole point of choosing between them. A defender who spills is promising that someone is waiting *outside*. A defender who boxes is promising that someone is waiting *inside*. In Figure 2 the same power play meets both.

¹Jon Svec, "Defending Split Zone" (January 12, 2022): spill players "fight INSIDE the blocker by using a Wrong Arm Technique," which requires another defender to take the gap outside; a boxing end "will fight hard to stonewall the [kick-out] and set the edge" with his "outside arm free": <https://jonsvec.substack.com/p/defending-split-zone>. Coaching vocabulary varies: some staffs say *squeeze* or *lever* for box technique, and *wrong-arm* or *wrong-shoulder* for spill.

Figure 2: Spill or box: the same power play against two techniques by the end man (the Sam, ringed in orange; the running back is ringed in green). Top row, spill: the Sam attacks the fullback's inside half in the backfield, the pile fills the hole, and the ball bounces outside to the strong safety, the force, with the Mike flowing over the top. Bottom row, box: the Sam squeezes down with his outside arm free and takes the kick-out at the line, the hole shrinks to a yard, and the Mike fills it and meets the pulling guard. Each technique sends the ball to a different teammate.

Follow the end man, ringed in orange, through both rows. In the top row he spills: he attacks the fullback before the fullback can get to him, takes him down in the backfield, and the pulling guard turns up into a lane already full of bodies. The back has nowhere to go but out, and out is where the strong safety, the force, is waiting with the Mike linebacker flowing over the top behind him. In the bottom row he boxes: he steps down, keeps his outside arm free and lets the fullback hit him at the line of scrimmage. The hole the play designed is still there, but it is a yard wide instead of three, and the Mike fills it downhill and meets the pulling guard right in it. The back has nowhere to go but straight into the collision.

Why choose one or the other?

Both techniques work. Both fail. The difference is *how* they fail, and a defense picks the failure it can live with.

Spill sends the ball to speed. A run that bounces sideways is running at the slowest angle in football: it gains no yards while it moves, and every defender on the field can chase it. Defenses with fast linebackers and safeties love to spill, because they would rather tackle a back in space with three pursuers than in a crowded hole with one. Spill also attacks the heart of a gap scheme. Power and counter depend on the puller turning up into a clean hole; take the hole away and the play's best blocker becomes a spectator. The risk is the outside. A spilled ball is going exactly where the defense has fewest bodies, and if the force is late, blocked or out of position, the back is around the corner with nobody between him and the end zone.

Box keeps the ball in the crowd. Boxing keeps everything inside, where the big bodies are, and it is simpler for the defenders outside: the force can stay outside and wait, because nothing is supposed to get to him. The risk is inside. A boxing end who gets driven off the ball (the kick-out does its job) leaves a hole wider than the one the play designed, and if the linebacker filling it is a step late or gets caught by the puller, the back runs through the middle of the defense untouched.

A common way to organize all this, though staffs differ, is a pattern coaches sometimes call *spill inside, force outside*: the players closest to the ball, linemen and inside linebackers, spill anything coming at them, and the outermost defender on each side boxes, so that every spilled ball runs into a man who keeps it from getting further out. In the top row of Figure 2, that is exactly the shape: the Sam spills, the strong safety boxes. The ball gets squeezed between them. Other defenses ask their end to box and their linebackers to spill the puller, and some change the call by formation or by opponent. What matters for you watching on Sunday is the promise each technique makes. When the end man wrong-arms a blocker, look outside for the man who has to be there.

💡 Watch for it

The tell is the end man's first contact. If he *dives under* the kick-out block toward the ball, it is a spill, and the run should bounce: watch for the force. If he stays square, outside arm free, and takes the block on his inside shoulder, it is a box, and the run should stay inside: watch the linebackers fill. When a broadcast shows a power run from the end-zone camera, the pile in the hole after a spill is impossible to miss.

The alley player

Spill a ball outside and it does not go straight to the force. It goes first into the space *between* the box and the force, a lane a few yards wide just outside the last defender on the line. Coaches call that lane the *alley*, and the defender responsible for it is the **alley player**: the man who fills the gap between the force player and the box, meeting a run that has bounced outside the box but not outside the force.

Look back at Figure 1. In the Cover 3 picture the strong safety is the force and the free safety, coming down from the deep middle, is the alley player; in some calls it is the Mike linebacker, flowing over the top. In the Cover 2 picture the cornerback is the force and the safety on that side is the alley player, coming down from his deep half. In quarters (Quarters and Match), the shape most of the NFL plays on early downs today, the outside linebacker or nickel back is usually the force and the safety is the alley player, who reads the tight end and fills downhill the moment he sees him block. Names and exact assignments differ by staff, and some defenses describe the same jobs with different words ("secondary contain," "fast" players, "lever").² The geometry does not differ. Every sound fit has, on each side of the ball, an outside man who forces and a man inside him who fills the alley.

Why does the alley player usually come from the secondary? Because he has to come from *outside the blocks*. The linebackers start in the box, where blockers can reach them: a pulling guard leads up on the Mike, a tight end climbs to the Will. A safety eight or twelve yards deep starts where no lineman can get to him before he reads the play. That is also what he costs. A safety filling the alley is not covering the deep zone he started in. Play-action, which Play-Action, Boots and Screens builds on exactly this, is the offense's way of sending a receiver into the space the alley player just left.

The fit chart: eleven defenders against power

Now put the pieces together for one play. Here is the same power play, right, against a 4-3 Over with a single-high safety, the strong safety down outside the tight end, and the end man (the Sam) told to spill. A coach would draw this as a **fit chart**: the play, with every defender's job written next to him. Figure 3 is the picture and the table under it is the chart. Read the table with the picture, one number at a time.

²For one widely shared clinic version of the vocabulary (force, "fast" players, secondary contain and alley players in an eight-man front, and the "lever-spill-lever" pattern), see coaching write-ups on run fits by coverage, for example Cody Alexander's MatchQuarters (<https://www.matchquarters.com>).

An 11-man fit chart: power right vs a 4-3 Over, Cover 3

Figure 3: An eleven-man fit chart against power right (the play of Gap and Power Runs), against a 4-3 Over with a single-high safety and the strong safety down. Blue: the blocks, the pulling guard and the running back's path. Orange arrows: where the defenders who move go. Rings: the spill player (orange), the force (purple) and the alley player (green). The numbers match the table below; every defender, including both cornerbacks, has a job.

#	Defender	Job against power right	Why it matters
1	Backside end (5-technique, left)	Unblocked. Squeeze down the line, flat, and chase; check the quarterback for a bootleg or keeper first.	Power leaves him free on purpose. He is too far away to stop the play, so his job is the cutback, the boot and the reverse.
2	Nose (1-technique, left)	Hold the backside A gap against the center's back block.	If he gets pushed out of it, the cutback has a lane right up the middle.
3	Defensive tackle (3-technique, right)	Anchor against the double team in the B gap: give no ground, keep both blockers busy.	Every second he holds two blockers is a second the right guard can't climb to the Will.
4	Play-side end (5-technique, right)	Fight the tight end's down block, squeeze the C gap, stay on the blocker's outside hip.	If he is washed inside, the hole doubles in size.
5	Sam (end man, right)	Spill : wrong-arm the fullback's kick-out, as deep in the backfield as he can.	The pile he makes is the wall that sends the ball outside.
6	Mike	Fast flow: run over the top of the pile, outside, ready for the bounce.	He is the second man in the alley. If the puller catches him, the safety has to be right.
7	Will	Slow flow: shuffle, own the backside A gap and the cutback, then pursue from behind.	The right guard's climb is aimed at him. If he over-runs the play, the cutback is open.
8	Strong safety	Force : come down outside-in, keep the ball inside him, turn the bounce back.	The spill only works because he is there.

#	Defender	Job against power right	Why it matters
9	Free safety	Alley: come down from the deep middle, inside-out, into the lane between the pile and the force.	Third man to the ball, and the last one between a bounce and a long run.
10	Right cornerback	Deep third. Read the receiver in front of him; if the Z blocks <i>in</i> on the safety (a crack block), he replaces the safety as the force.	The crack-and-replace rule keeps the edge from going empty when the offense blocks the force.
11	Left cornerback	Deep third on the backside: no deep pass behind him, then the last defender on any cutback that breaks.	Somebody has to stay home on a play-action pass.

This is a typical way to fit the play, not one team's playbook: defenses vary the spill and box calls, who flows where, and which safety comes down.

Three things are worth noticing.

Everybody has a job, including the players far from the ball. The left cornerback is fifteen yards from the play and still has an assignment, and if he leaves it to chase the run, a play-action pass to the X receiver is a touchdown. Fits are eleven-man plans, which is why defensive coaches say a run defense is only as good as its worst fit.

The defense counts, and so does the offense. Power brought seven blockers to the party (five linemen, the tight end and the fullback). The defense brought eight defenders into and around the box (four linemen, three linebackers and the strong safety), plus a free safety who can arrive late. That eighth defender is the subject of the next section, but look where the defense spends him: as the force, *outside* the play, exactly where a spilled ball ends up. The fit chart and the box count are the same idea seen from two sides.

Gaps move, and the fits move with them. Before the snap, the Mike was over the right A gap. After the snap, the right A gap has a nose, a tackle and two linemen in it, and the Mike's job is outside the pile, three gaps over. He did not freelance. He read his key, saw power, and went where the plan said power's gap would appear. Every linebacker's read in Linebackers and the Second Level is a question about where his gap has gone.

Fits against zone: when the gaps keep moving

Power tells the defense where it is going. A pulling guard is a signpost, and a defense that reads it can fit the gap the play creates. Zone does the opposite. As Zone Running showed, the whole line steps the same way and the running back picks the hole *after* the snap, so there is no single gap to fit. The gaps slide sideways with the blockers, and the back is reading the defenders to see which one is out of place.

Against zone, then, a fit is less a spot than a relationship: *stay on the correct side of your blocker, and stay a gap behind the ball.* Figure 4 draws it against outside zone.

Fitting outside zone: the gaps move, so the fits move

Figure 4: Fitting outside zone right. The line steps right and the back aims wide, so the gaps slide with the blockers. The play-side end stretches with the reach and keeps his outside arm free; the Sam is the force (purple ring), coming up outside-in; the Mike flows fast but stays a gap behind the ball; the Will slow-flows and owns the cutback (green ring), with the backside safety behind him in the cutback alley; the backside end squeezes, chases and watches for the bootleg.

- **The play-side edge doesn't spill.** There is no kick-out to spill. The tight end or tackle is trying to *reach* the end man, get his head outside and seal him in. So the end man stretches with the reach, keeps his outside arm free and makes the ball cut up inside him. The Sam outside him is the force, coming up outside-in to stop the back from winning the corner. Together they squeeze the run back toward the middle, where the outside zone runner does not want to be.
- **The play-side linebacker runs, but behind the ball.** Fast flow, but never ahead of the running back's helmet. A linebacker who over-runs the play (gets outside the ball) has given the back a lane behind him, and zone is designed to find exactly that lane.
- **The backside owns the cutback.** This is where zone hurts defenses. Outside zone's biggest runs are cutbacks, so the backside linebacker slow-flows (shuffles, waiting) and owns the cutback lane, and the backside safety comes down into the alley behind him. The backside end squeezes down the line, chasing from behind, but with one eye on the quarterback: outside zone's best friend is the bootleg the other way.

Zone also explains the most common *failure* of gap integrity on a broadcast. When a zone run gets eight yards on a cutback, rewind and look at the backside linebacker. Usually he flowed with everyone else, two defenders ended up in the same play-side gap, and the backside gap he owned was empty. The back didn't make the hole. The defense gave it to him.

The plus-one: where the extra defender comes from

So far this chapter has assumed something it hasn't said out loud: the defense has enough players to own every gap and still have someone left over. Where does that someone come from?

The Language of the Run Game introduced hat math: count the offense's blockers, count the box, and compare. A First Look at Defense turned it into a scale (light, normal, loaded). The defensive side of that arithmetic has a name. The **plus-one** is having one more run defender than the offense has blockers, so one defender is unblocked and free to make the tackle. With six blockers, it means seven run defenders; with seven, eight.

Why one *more*? Because if the numbers are even, every defender can be blocked. A hat on every hat means the runner reaches the second level untouched unless some defender beats his blocker, and the defense would be betting its whole run defense on winning one-on-one fights. With a plus-one, the defense doesn't need to win a single block. It needs every defender to hold his gap, and the extra man makes the tackle. Look at the fit chart again: the strong safety is the plus-one, and his job, force, is the one nobody on the offense was assigned to block.

The plus-one almost always comes from the secondary, because that is where the spare players are. The defense starts with eleven; the corners are usually busy with the wide receivers, and one deep safety stays back to prevent the long pass. Everyone else can be a run defender. So the cleanest way to add a defender to the box is to bring a safety down, and the cleverest way is to bring him down *at the snap*, after the quarterback has looked at the defense.

The plus-one: a safety rotates into the box at the snap

Figure 5: The plus-one. Before the snap the defense shows two high safeties and six defenders in the box (shaded) against six blockers: a light box. At the snap the strong safety rotates down (arrow) to the spot ringed in purple, just outside the tight end, and the free safety rotates to the deep middle. The box is now seven against six, with one defender nobody is assigned to block.

In Figure 5 the defense shows two high safeties before the snap. Count the box: four linemen and two linebackers, six defenders against six blockers (five linemen and the tight end). That is a light box, and a quarterback with the freedom to check to a run at the line would be tempted. At the snap, the strong safety rotates down into the box and the free safety slides to the deep middle. Now it is seven against six, the plus-one, and the shell has turned from two-high into one-high. How the defense hides that move until the last moment, and the names for the many ways to do it (a *sky* rotation, a *spin* on motion), are the subjects of Cover 3 and Disguise and Rotation.

The offense's answers, and the defense's answers to those

The plus-one is not a fixed fact. It is the opening position in a negotiation, and each side has a short list of moves.

The offense can add a blocker. A second tight end or a fullback makes seven blockers, so the defense needs eight to stay plus-one. That is why heavy personnel is a run-game tool, and why it came back: in 2025 NFL offenses used fewer than three wide receivers on 41.7% of plays, the first season at or above 38% since Next Gen Stats began tracking in 2016.³

³James Reber, Next Gen Stats, "NFL trend watch: heavy personnel" (February 2026): offenses used fewer than three wide receivers on 41.7% of plays in 2025: <https://www.nfl.com/news/nfl-trend-watch-heavy-personnel-could-shape-super-bowl-lx-showdown-between-patriots-and-seahawks/planning/FACTS-current.md> §10).

The offense can spread the defense out. Every receiver split wide pulls a defender with him. Four wide receivers leave the defense with fewer players to put in the box at all.

The offense can read the free man instead of blocking him. This is the option idea from Option Football, and it is the plus-one's natural enemy. If the quarterback reads the unblocked defender and keeps the ball whenever that defender chases the back, the offense has "blocked" him without spending a blocker, and the count is even again. So the rule of box math with a running quarterback is simple: **count the quarterback as a blocker**. Six blockers plus a quarterback who reads is seven.

The offense can throw. Every safety in the box is a safety not covering a deep zone. The run-pass option (RPOs) and play-action both turn the plus-one into a target.

And the defense's answers? It can bring yet another safety, and play with no deep safety at all, a gamble you will meet in Blitz and Man Pressure. It can change the *technique* instead of the numbers: two-gapping linemen who each control two gaps let six defenders cover seven gaps, which is the whole idea behind the tite front of Odd and Hybrid Fronts. Or it can accept the light box and fit the run from depth, which is the next section, and the biggest strategic argument in the NFL right now.

Fitting the option: the gap exchange

The zone read is plus-one arithmetic with a quarterback in it. Option Football showed the offense's view: block everyone but the backside end, read him, and hand the ball to whichever runner he is not taking. The defense's fit chart has to say who takes the running back and who takes the quarterback, and the simplest version says the end takes the quarterback (he stays home) and the linebacker behind him takes the inside gap. The offense knows that chart, so the end's behaviour tells the quarterback what to do.

The defense's answer is to change the chart after the snap. A **gap exchange** is a planned swap of gap responsibilities between two defenders after the snap: one takes the other's gap and vice versa. The best-known version is the scrape exchange from 03-04: the end crashes inside at the running back, which is the "keep" read, and the linebacker behind him scrapes over the top to take the quarterback. Figure 6 runs it as a fit. The tags show what each defender owns, before the snap and after it.

Figure 6: The scrape exchange as a run fit (simulated). The line zones right and the quarterback reads the backside end. The tags show who owns what: before the snap the end has the quarterback and the Will (ringed in orange) the inside gap; at the snap they swap. The end crashes on the back, the quarterback (ringed in green) sees 'keep' and pulls the ball, and the Will, scraping over the top, meets him. The left guard climbs to where the Will used to be and finds nobody.

The quarterback did everything right. He read the end, the end took the back, and he kept the ball. The defense simply moved the man who owned the quarterback, and it did it after the quarterback's eyes had stopped looking for him. Notice the cost, too, in the last frame: the left guard climbed to the spot where the Will used to be and found nobody. The Will's original gap, the backside B gap, was empty for a moment. If the back had kept the ball (if the end had stayed home after all, or the quarterback had handed off), that gap would have been the hole. A gap exchange is a bet that the offense will read the *first* picture.

Gap exchanges are not only for the option. A defensive line slant (05-01) is a gap exchange for a whole front: every lineman moves over one gap and the linebackers move the other way to fill what they left. An end who "spikes" inside while the outside linebacker takes his C gap is one; so is a linebacker who blitzes through the A gap while the nose loops into the B gap. The idea is always the same: keep gap integrity (every gap still has exactly one owner) while changing *which* defender owns it, so the blocking scheme and the quarterback's read, both built on the pre-snap picture, are wrong. That is also the logic of the simulated pressures of Part 7, applied to the pass game.

Against a team built on the option, defenses also rewrite the chart in option language. Instead of gaps, a coach assigns *dive* (the running back on the inside run), *quarterback* and, if there is one, *pitch*, and he makes sure each has an owner on every play, with the assignments rotating between players from snap to snap so the quarterback never sees the same picture twice. That is the logic you will see from the defensive side of The Ravens' Option Run Game.

Two-high and the light box: inviting the run on purpose

Everything so far says the defense wants a plus-one in the box. For most of football history, that was the end of the discussion. Then, starting in the late 2010s, more and more NFL defenses began doing something that looked backward: keeping both safeties deep, playing six (sometimes five) defenders in the box against six blockers, and daring the offense to run.

Here is the shape of it.

Two-high, light box: the plus-one comes from 12 yards away

Figure 7: The two-high light box against inside zone. Six blockers, six defenders in the box: the guards climb to the linebackers and every defender has a blocker. The defense's free men are the two safeties (purple rings), filling from 12 yards. By the time they arrive, the run has reached the shaded area, four or five yards downfield: the yards the defense has agreed to give.

In Figure 7 the box is even: six defenders, six blockers, a hat on every hat. Nobody in the box is free. The plus-one still exists, but it is twelve yards away: the two safeties, who read run and come downhill as alley players. They are the defense's free men, and they arrive late, somewhere around four or five yards downfield. The defense has done the box math and decided to pay a few yards on every run in exchange for something it values more.

Why a defense would do this

Explosive passes cost more than runs. Expected Points and Success Rate showed that the average pass gains more than the average run, and the big losses for a defense are explosive pass plays. Two deep safeties are the best protection against them. A defense that keeps two high is choosing to give up four-yard runs rather than forty-yard passes. You will see in the data below that this is a sensible trade.

Two-high shells can disguise. A defense that shows two safeties can still rotate into one-high at the snap (the plus-one of Figure 5) or play any of the two-high coverages behind it. The light box keeps the offense guessing about who will be in it a second after the snap.

It has been spreading. Next Gen Stats measured split-safety coverage on 32.9% of plays in 2018, 40.4% in 2024 and 42.0% in 2025, the highest since its tracking began.⁴ The box counts moved with it: in the nflverse data, designed runs met six or fewer defenders in the box about 38% of the time in 2018–2022, and 58% and 55% of the time in 2024 and 2025.⁵

⁴NFL Next Gen Stats, split-safety coverage rate: 32.9% (2018), 40.4% (2024), 42.0% (2025): <https://www.nfl.com/news/the-coverage-that-turned-the-seahawks-into-super-bowl-winners-and-is-taking-the-nfl-by-storm>.

⁵This book's calculation from nflverse play-by-play joined to participation data (`defenders_in_box`), regular-season designed runs (quarterback scrambles and kneels excluded): six or fewer in the box on 37–40% of designed runs each season from 2018 to 2022, 43% in 2023, 58% in 2024 and 55% in

The coach most associated with the approach is **Vic Fangio**, an NFL assistant for more than thirty years before Denver made him a first-time head coach at 60 (2019–2021), whose two-high defenses in Chicago and Denver were copied across the league by the coaches who worked for him.⁶ His approach is simple to state: keep two safeties deep to take away the explosive pass, and ask the front to hold the run without help. His linemen are asked to win their own fights and, at times, to “steal” back gaps the box does not have bodies for, as a Philadelphia beat writer put it in 2024.⁷ How the counterrevolution started, and the answer to it, are history for The Modern Era and a case study, Fangio’s Two-High Revolution and Macdonald’s Answer.

What it costs

The light box is a trade, and the bill comes in four parts.

- **Yards.** Runs against six-man boxes average more than runs against seven or eight: on early downs in the data below, about a quarter of a yard more per carry than against seven and more than half a yard more than against eight or more. A defense that lives in light boxes will look bad in rushing yards allowed, and it has accepted that.
- **The front must be good enough to hold.** A six-man box has no margin. If one lineman is moved off his gap, there is no spare linebacker behind him; the next defender is a safety at twelve yards. Light-box defenses need linemen who can take on double teams and two-gap when they have to, which is why they pay for big interior players and why the tite front of Odd and Hybrid Fronts became their favourite shape.
- **The safeties must tackle.** A safety fitting from depth meets the runner at full speed, in space, often one-on-one. A missed tackle there is not a four-yard run. It is a forty-yard run, because there is nobody behind him.
- **Heavy personnel attacks it.** Against a light box, the offense’s simplest move is to add blockers, and the rise of two- and three-tight-end sets in 2024 and 2025 is partly that. Each extra blocker forces the defense to choose again: match it with a heavier package (base defense was on the field for 29.7% of snaps in 2025, up from a low of 20.5% in 2023) or accept being outnumbered in the box.⁸

Common misconception

“A light box means the defense is soft against the run.” The 2024 Eagles faced runs with six or fewer defenders in the box about two thirds of the time, among the three highest rates in the league, and allowed the fewest expected points per designed run of any defense, by this book’s count.⁹ A light box is not the absence of a run fit. It is a fit that uses the safeties instead of an eighth man at the line, and that asks more of the defensive line.

What the data says: box count and EPA

You can test all of this with the nflverse data. The participation files record how many defenders were in the box at the snap on almost every play, and the play-by-play records the result. Figure 8 compares designed runs and dropbacks by box count, on first and second down in neutral situations (so that third-and-long and the goal line, where box counts and outcomes are both extreme, don’t tilt the picture), for two eras of the data that count the box in slightly different ways.

2025. The box count comes from Next Gen Stats through 2022 and from FTN charting from 2023, so part of the change may be how the box is counted; the jump from 2023 to 2024 is within the FTN years.

⁶Fangio (born 1958): San Francisco defensive coordinator 2011–2014, Chicago defensive coordinator 2015–2018, Denver head coach 2019–2021, Eagles consultant 2022, Miami defensive coordinator 2023, Philadelphia defensive coordinator from 2024 (still in 2026, planning/FACTS-current.md §9): https://en.wikipedia.org/wiki/Vic_Fangio.

⁷EJ Smith, “Eagles run defense ... Vic Fangio,” *Philadelphia Inquirer* (September 19, 2024): a light box forces the linemen to “win at the point of attack and, at times, ‘steal’ back gaps”: <https://www.inquirer.com/eagles/eagles-run-defense-vic-fangio-jalen-carter-falcons-bijan-robinson-20240919.html>.

⁸Next Gen Stats (Reber), same article as above: defenses played base on 29.7% of plays in 2025, against a low of 20.5% in 2023 (planning/FACTS-current.md §10).

⁹This book’s calculation from nflverse play-by-play and participation data, 2024 regular season, opponents’ designed runs: the Eagles faced six or fewer in the box on 66% of them (third-highest rate; league 58%) and allowed –0.18 EPA per designed run, the lowest of the 32 defenses.

Figure 8: EPA per play by the number of defenders in the box at the snap, regular seasons 2018–2025, first and second down, win probability 20–80%, outside the last two minutes of each half and outside the opponent’s 10-yard line. Left: designed runs (quarterback scrambles excluded). Right: dropbacks (passes, sacks and scrambles). Each extra defender in the box costs runs about 0.03 to 0.05 expected points and is worth about the same to the passing game, the box as a budget. Even against the lightest boxes, runs average less than dropbacks do against the heaviest. The two lines are the two data sources (NGS for 2018–2022, FTN for 2023–2025), which count the box slightly differently; bars are 95% intervals. Data: nflverse play-by-play and participation via nflreadpy.

Read the left panel first. The more defenders in the box, the worse runs do: on these downs, designed runs averaged about -0.03 EPA against five or fewer in the box, -0.05 against six, -0.09 against seven and -0.15 against eight or more, and their success rates fell from about 41% to 34% across the same range.¹⁰ Both data sources agree on the slope. The plus-one is real: each defender the defense adds to the box takes something away from the run.

Now the right panel, which is the part that explains the two-high era. The same extra defender *helps the passing game*. Dropbacks against five or fewer in the box averaged about $+0.06$ EPA; against seven, about $+0.12$; against eight or more, about $+0.16$ in the 2018–2022 data. The box is a budget: a defender spent near the line is a defender not spent in coverage, and the offense’s passing game cashes the difference. (The 2023–2025 point for eight or more dropbacks rests on only about 800 plays, which is why its interval is so wide.)

And look at the two panels side by side. **Against every box count, the average dropback beats the average designed run.** Even against the lightest boxes, runs averaged less than zero EPA; even against the heaviest, dropbacks averaged more than zero. That is the quiet argument for the light box. A defense that keeps two safeties deep and invites the run is steering the offense toward its less efficient option, and paying for it with a few yards per carry that, on average, are worth less than the passes it took away.

Three cautions keep this honest.

- **The box count is measured at the snap.** A safety who rotates down after the snap, like the one in Figure 5, is counted *out* of the box. Some “six-man boxes” in the data were seven-man fits a second later, which makes light boxes look a little better against the run than the fits really were.
- **Boxes are chosen, not assigned at random.** Defenses load the box when they expect a run and empty it when they expect a pass, and offenses check into runs against light boxes. Holding the down and the game situation fixed, as this chart does, removes the worst of that, but not all of it. A First Look at Defense showed how flat these comparisons look when you don’t.
- **The data changes source between 2022 and 2023.** Next Gen Stats supplied the box count through 2022, FTN’s charts from 2023, and they draw the box differently, so read the two lines as two measurements, not one trend.

¹⁰This book’s calculation, same filters as the chart, both eras pooled: designed runs averaged -0.03 , -0.05 , -0.09 and -0.15 EPA against 5-or-fewer, 6, 7 and 8-or-more defenders in the box (success rates 41%, 40%, 37% and 34%; 5.1, 4.8, 4.6 and 4.2 yards per carry; about 1,600, 21,800, 20,100 and 6,700 runs). Dropbacks averaged $+0.06$, $+0.08$, $+0.12$ and $+0.16$ EPA.

i Go deeper

Finding the force in tracking data. The “Watch for it” rule (the outermost defender near the line on each side, inside the widest receiver, is probably the force) is easy to turn into code. Here it is run on the simulated play in Figure 3, exported in Big Data Bowl format (these frames are simulated, BDB-format, not real tracking):

	side	probable force	yards outside the ball	depth
offense's right		SS	9.5	6.5
offense's left		WE	4.0	1.0

On the right it finds the strong safety, the force in the fit chart; on the left, with no tight end and a deep corner, it finds the backside end. With real Big Data Bowl files the same function works on a prepared play (this cell is not run in the build):

Film room

i Film room: Seattle Seahawks 2012–2015 (the eighth man)

The plus-one’s most famous modern home was Pete Carroll’s Seattle defense, built on single-high Cover 3. Earl Thomas played the deep middle, alone, and Kam Chancellor, a strong safety built like a linebacker, played near the line as the eighth man in the box. Seattle led the NFL in scoring defense four years running, 2012 through 2015.¹¹ Watch any of their games from those seasons for one thing: where Chancellor is at the snap. He is the force on runs to his side, the plus-one in the box count, and the reason offenses that wanted to run on Seattle needed an extra blocker. Then watch what happens to Thomas when the offense fakes the run: he is the only deep defender, which is the cost of the eighth man.

i Film room: Philadelphia Eagles 2024 (the light box that held)

Vic Fangio’s first Eagles defense, in 2024, is the light-box argument at full strength. Through the first three weeks the *Philadelphia Inquirer* counted six or fewer defenders in the box on 73.5% of snaps, the third-highest rate in the league, and the run defense looked shaky after the Falcons ran through it in Week 2.¹² Over the full season, by this book’s count, opponents’ designed runs met six or fewer in the box about two thirds of the time (the third-highest rate), and the Eagles allowed the fewest EPA per designed run in the league. Every defense Fangio has run since 2019 (he spent 2022 as a consultant) has been among the five that met runs with six or fewer in the box most often.¹³ What to watch: the two safeties at 12–14 yards at the snap, the six-man box, and how often an interior lineman ends up with two blockers on him and doesn’t move. The defense is betting on the front, and in 2024 the bet paid off on the way to a Super Bowl LIX win over Kansas City, 40–22.

¹¹“Seattle Cover 3 defense,” Wikipedia (the scheme of Pete Carroll and Dan Quinn; Seattle led the NFL in scoring defense from 2012 to 2015; Thomas as the post safety, Chancellor in the box): https://en.wikipedia.org/wiki/Seattle_Cover_3_defense; “Legion of Boom,” Wikipedia: https://en.wikipedia.org/wiki/Legion_of_Boom.

¹²EJ Smith, *Philadelphia Inquirer*, September 19, 2024 (cited above): six or fewer in the box on “73.5% of the time, which is the NFL’s third-highest rate,” written after the Eagles’ Week 2 loss to Atlanta.

¹³This book’s calculation from nflverse play-by-play and participation data, regular seasons, opponents’ designed runs: the share of runs Fangio’s defenses faced with six or fewer in the box ranked 5th (Denver 2019), 2nd (2020), 3rd (2021), 2nd (Miami 2023), 3rd (Philadelphia 2024) and 3rd (2025) of 32 defenses; by average box count, 7th, 2nd, 3rd, 10th, 5th and 5th lightest. EPA per designed run allowed ranked 1st in 2024 and 7th in 2025. Super Bowl LIX, Eagles 40, Chiefs 22: [planning/FACTS-current.md §1](#).

i Film room: Baltimore Ravens 2019 (the box that wasn't loaded enough)

The 2019 Ravens rushed for 3,296 yards, breaking an NFL team record that had stood since 1978, and Lamar Jackson ran for 1,206 of them on his way to a unanimous MVP.¹⁴ Box math explains why defenses could not simply load up. On a designed run with Jackson reading a defender, every box needed one more defender than it appeared to, because the quarterback counts as a blocker. Defenses met the Ravens' designed runs with seven or more in the box about 65% of the time, slightly more than they did the rest of the league, and still lost: the Ravens averaged about +0.10 EPA per designed run against seven-man boxes and about +0.04 against eight or more, where the league averaged -0.10 and -0.13. Jackson's own designed runs averaged about 7.1 yards.¹⁵ What looks like a normal seven-man box on the broadcast was, against Baltimore, a light one. Watch any 2019 Ravens game for the defender the quarterback is reading, and count him out of the box.

i Film room: Philadelphia Eagles 2024 offense (running at two-high)

The same season, on the other side of the ball, the Eagles showed what a good run game does to a light box. Saquon Barkley ran for 2,005 yards, the ninth 2,000-yard season in NFL history.¹⁶ Against Philadelphia, defenses played six or fewer in the box on about 61% of designed runs (the league rate was about 59%), and the Eagles averaged about 5.4 yards per designed run against those boxes, against the league's 4.6. About one in seven of those runs gained ten yards or more.¹⁷ That is the light box's bill, paid in full: when the front cannot hold six blockers and the safeties arrive at five yards instead of three, the runs that get past them go a long way. What to watch: the safeties' depth at the snap, the double teams on the interior, and the moment Barkley reaches the second level one-on-one with a safety coming downhill.

Watch for it on Sunday

💡 Watch for it

Before the snap

- **Count the box, then count the blockers.** Five linemen, plus every tight end and fullback near the line. If the quarterback is a runner who reads a defender, add him. More defenders than blockers: the defense has its plus-one in the box. Even: the plus-one is a safety, and he will arrive late.
- **Find the force on each side.** Look for the outermost defender within about seven yards of the line and inside the widest receiver. A safety walked down outside the tight end: safety force (likely Cover 3). Corners squatting at five yards with both safeties deep: corner force (likely Cover 2). Nobody out there but the end: the end is the force.
- **Check the safeties' depth.** At 12–14 yards, they are alley players from depth and the box is what you see. At 8–10 yards and creeping, one of them is probably coming down at the snap.

After the snap

- **Did a safety rotate down?** That is the plus-one arriving.
- **Watch the end man meet the kick-out or the puller.** Dives under it: spill, so look outside for the force. Stays square, outside arm free: box, so look inside for the linebacker filling.
- **Did the run bounce?** If it did, who met it outside, the force or nobody? If nobody, rewind and find the empty gap.
- **On a cutback, find the backside linebacker.** If he flowed with everyone else, that is the gap the runner used.

¹⁴"Ravens break single-season team rushing record," NFL.com (3,296 yards, breaking the 1978 Patriots' 3,165): <https://www.nfl.com/news/ravens-break-single-season-team-rushing-record-0ap3000001092761>; Jackson's 1,206 rushing yards and unanimous MVP: https://en.wikipedia.org/wiki/2019_Baltimore_Ravens_season. The era is closed: John Harbaugh was fired in January 2026 (planning/FACTS-current.md §0, C3).

¹⁵This book's calculation from nflverse play-by-play and participation data (Next Gen Stats box counts), 2019 regular season, designed runs: Baltimore faced seven or more in the box on 65% (league 62%); EPA per designed run +0.10 against seven (league -0.10) and +0.04 against eight or more (league -0.13); Baltimore led the league at +0.09 EPA per designed run overall. Jackson: 120 designed runs, 7.1 yards per carry.

¹⁶NFL.com, "Saquon Barkley becomes ninth player to rush for 2,000 yards in a season": <https://www.nfl.com/news/saquon-barkley-becomes-ninth-player-to-rush-for-2000-yards-in-a-season>.

¹⁷This book's calculation from nflverse play-by-play, participation and FTN charting, 2024 regular season, designed runs excluding quarterback sneaks (FTN is qb_sneak): Philadelphia ran into six or fewer in the box on 61% (league 59%), averaging 5.4 yards (league 4.6) with 14% gaining 10 or more yards (league 11%); against seven or more, 4.6 yards. Barkley averaged 5.9 yards against six or fewer.

Predict the play

💡 Predict the play

Drill 1. Who's the force? First-and-10, 11 personnel. The offense is about to run outside, to its right, toward the tight end and the Z receiver. Before the snap the defense shows the picture below. Who is the force on the play side, who is the alley player, and where do you expect the run to end up?

Drill 1: who forces a run to the right?

Figure 9: Drill 1: before the snap. Both safeties are deep, 12 yards off the ball and outside the hashes; both corners are squatting at about 5 yards, a step outside their receivers, facing the quarterback; six defenders in the box against six blockers.

Answer 1 is at the end of the chapter. Try it first.

💡 Predict the play

Drill 2. Do the box math. Second-and-6. The offense is in shotgun with 11 personnel, and its quarterback is one of the league's most dangerous runners. The defense shows two high safeties and six defenders in the box. How many blockers does the offense really have, who is the defense's free man, and what run do you expect?

Drill 2: count the box, then count the blockers

Figure 10: Drill 2: before the snap. Shotgun, one back beside the quarterback, a tight end on the right; four defensive linemen and two linebackers in the box, a nickel back outside it on the left, two safeties at 12 to 13 yards.

Answer 2 is at the end of the chapter. Try it first.

💡 Predict the play

Drill 3. The force is the target. First-and-10. The offense is in the I-formation and the defense is in a single-high shell with the strong safety down outside the tight end, the shape of Figure 3. One thing is different: the Z receiver has lined up much closer to the formation than usual. What is the offense planning, and who on the defense has to be ready?

Drill 3: why is the Z so close?

Figure 11: Drill 3: before the snap. 21 personnel in the I-formation; a 4-3 Over with the strong safety down at about 6 yards outside the tight end and one deep safety. The Z receiver is in a tight split, about 9 yards from the ball instead of out near the numbers.

Answer 3 is at the end of the chapter. Try it first.

Back to the replay

Return to the opening play. The offense ran power to the right; the end man threw himself under the fullback; the back bounced outside and was tackled by a safety who started twelve yards deep. Now you can name every piece of it. The end man was the **spill** player, and the pile he made was the point: the pulling guard had no lane, and the ball went sideways. The safety who made the tackle was either the **force** (if he had come down to the edge) or the **alley player** (if he filled the lane inside the force from depth), and he had been free all along, the defense's **plus-one**, never assigned to any blocker. The analyst said "great fit" because every defender between the ball and the sideline did his job and nobody did anyone else's. Nobody beat a block. The arithmetic did the work.

Takeaways

- **A run fit is an eleven-man plan.** Every gap has exactly one owner (gap integrity), and every owner knows how his gap moves when the blocking changes. Two defenders in one gap means an empty gap somewhere else.
- **Force turns the ball back inside.** The force defender is a role, not a position: the end, a linebacker, a safety or a corner, depending on the call. The coverage usually decides who is free to be him (safety force in Cover 3, corner force in Cover 2).
- **Spill and box send the ball to opposite places.** Spill wrong-arms the kick-out and bounces the ball outside to speed; box keeps the outside arm free and squeezes the ball inside to the linebackers. Each is a promise about who is waiting, and the alley player fills the lane between the box and the force.

- **The plus-one is the extra defender, and it usually comes from a safety.** Offenses erase it with an extra blocker, a quarterback read or a pass; defenses get it back with rotation, gap exchanges or two-gapping fronts. Count the quarterback when he runs.
- **The light box is a bet, not a mistake.** Two-high defenses give up a few yards per carry to protect against the explosive pass. In 2018–2025 data, each extra box defender cost runs about as much as it gave passes, and the average dropback beat the average run at every box count.

Connections

Builds on: Linebackers and the Second Level (keys, flow, fill and scrape: how the second level gets to its gaps), Option Football (the read and the scrape exchange), Gap and Power Runs and Zone Running (the plays these fits answer), Defensive Line Play (setting the edge, fighting a down block, slants), and A First Look at Defense (the box and the shells).

Sets up:

- Cover 3, Cover 2 and Tampa 2 and Quarters and Match: each coverage chapter says who the force and the alley player are, because the coverage decides it.
- Disguise and Rotation: how a defense hides which safety will be the plus-one until the snap.
- Zone Blitz and Simulated Pressure: gap exchanges aimed at the pass protection instead of the run.
- Constraint Theory and Sequencing: play-action and RPOs as the offense's answer to defenders whose run fits pull them out of coverage.
- The Modern Era: the two-high counterrevolution and the light-box run game.

See also (case studies): The Ravens' Option Run Game, box math with a quarterback who counts as a blocker; and Fangio's Two-High Revolution and Macdonald's Answer, the light box as a whole defensive philosophy.

If you want to go deeper: Cody Alexander's MatchQuarters site and books, the most thorough public writing on how two-high defenses fit the run; Jon Svec's short essays on defending specific run schemes, spill and box included; Chris B. Brown's *The Art of Smart Football* on how run schemes and defenses answer each other; and any broadcast's end-zone replay of a power run, watched only for the end man and the man outside him.

Answers to Predict the play

Answer 1.

The right cornerback is the force; the strong safety is the alley player. Two deep safeties and two corners squatting at five yards, outside their receivers, with their eyes on the quarterback is the classic Cover 2 shape. The corners have no deep zone to protect, so the play-side corner is free to come up outside-in, keep the ball inside him and turn it back. The strong safety, starting at twelve yards, reads run and comes down into the alley between the corner and the box.

Expect the run to be turned back inside around the numbers, and expect the defense to *give up some yards* doing it: six in the box against six blockers is a light box, and the alley player is arriving from twelve yards. The offense's best counter is a receiver blocking the corner (the Z cracking down, or simply blocking him out), which is why, against Cover 2, the wide receivers' blocks matter so much in the run game. One caution: corners squatting at five yards can also be a disguise, bailing to deep thirds at the snap (Disguise and Rotation). If that happens, the force becomes whoever rotates down, usually a safety.

Answer 2.

Seven blockers against six, and the free men are twelve yards away. Five linemen and the tight end make six blockers, and the box holds six defenders: even. But a quarterback who runs and reads counts as a blocker, because the defender he reads is "blocked" by the read. So on a zone read the offense is effectively seven against six, plus-one *in the offense's favour*. The defense's free men are the two safeties.

Expect a zone read, or a run with the quarterback as a threat, and expect it to gain four or five yards before a safety arrives, unless the defense has a plan. Its plans: rotate a safety down at the snap (watch for one creeping toward 8–9 yards before the ball is snapped), or exchange gaps on the read man (the end crashes, a linebacker scrapes to the quarterback, Figure 6). If the safeties stay deep and the end sits still, this is the Ravens' 2019 picture, and it is a good one for the offense.

Answer 3.

A crack block on the force, so the cornerback must replace him. The defense's fit against power depends on the strong safety: he is the force, the man outside the spill. A receiver in a tight split is in perfect position to block *down* on him at the snap,

a crack block (Perimeter Runs and Misdirection), from the side, where the safety is not looking. If the defense spills the kick-out and the force has been cracked, the bounce has nobody outside it.

So the defender who must be ready is the right cornerback. His rule is *crack-replace*: when the receiver in front of him blocks in, he stops thinking about his deep third and comes up to become the force himself. Many defenses also check out of the spill call when a receiver cracks, boxing the kick-out instead so the ball stays inside. Watch the corner's first step after the snap. If it is forward and outside, the defense saw the crack coming. If it is backward, the run is going to the sideline.
